

Clinical application Of QLF technology

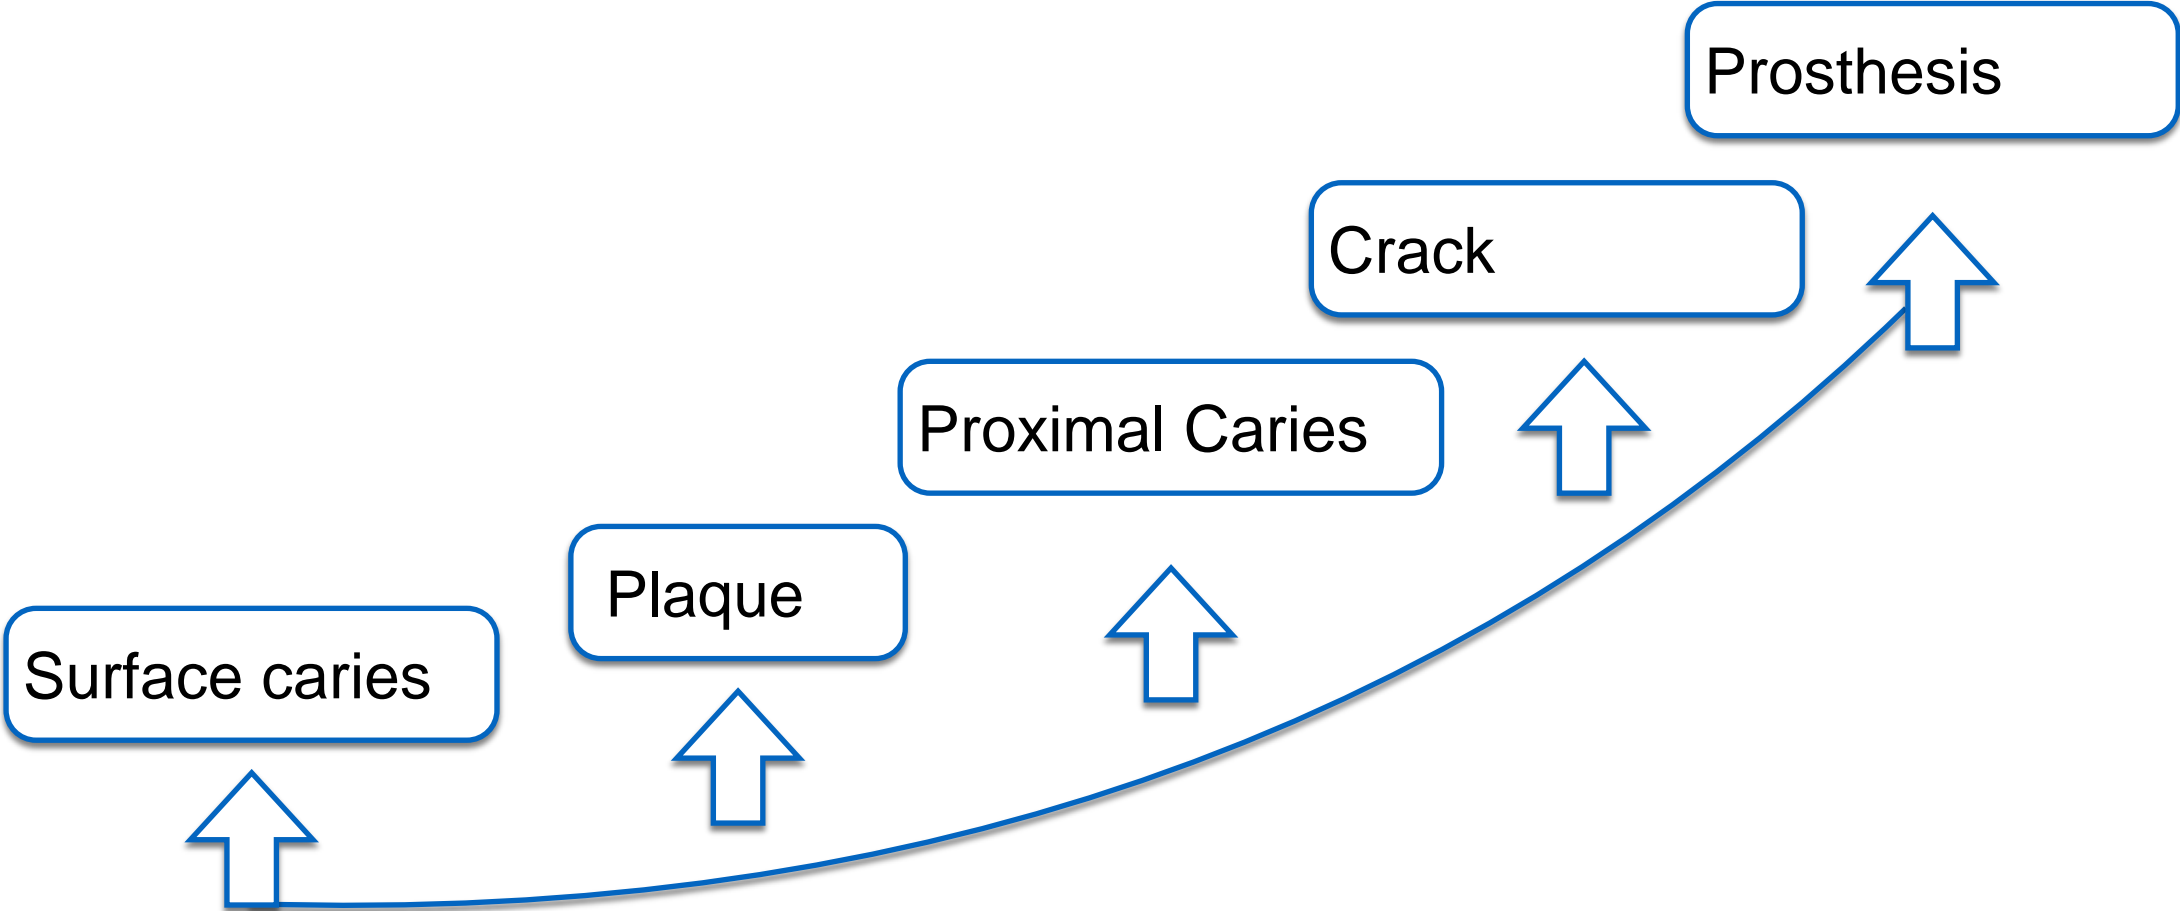

Oral Health Care Assistant

Qscan directly reveals incipient caries, plaque, tartar, tooth fractures and denture cracks through red fluorescence. This is equipment specifically developed for the patient to use him or herself at home.

Dr. Hongcheol Yoon
PhD, Prosthodontist
Private practitioner (BestDen Dental Clinic, Seoul)

Proximal caries

Proximal caries

Objective

To assess the screening performance of the QLF technology to detect **proximal caries** in a clinical situation and to propose QLF score for the proximal caries (**QS-Proximal**).

65 subjects, 280 proximal surface:

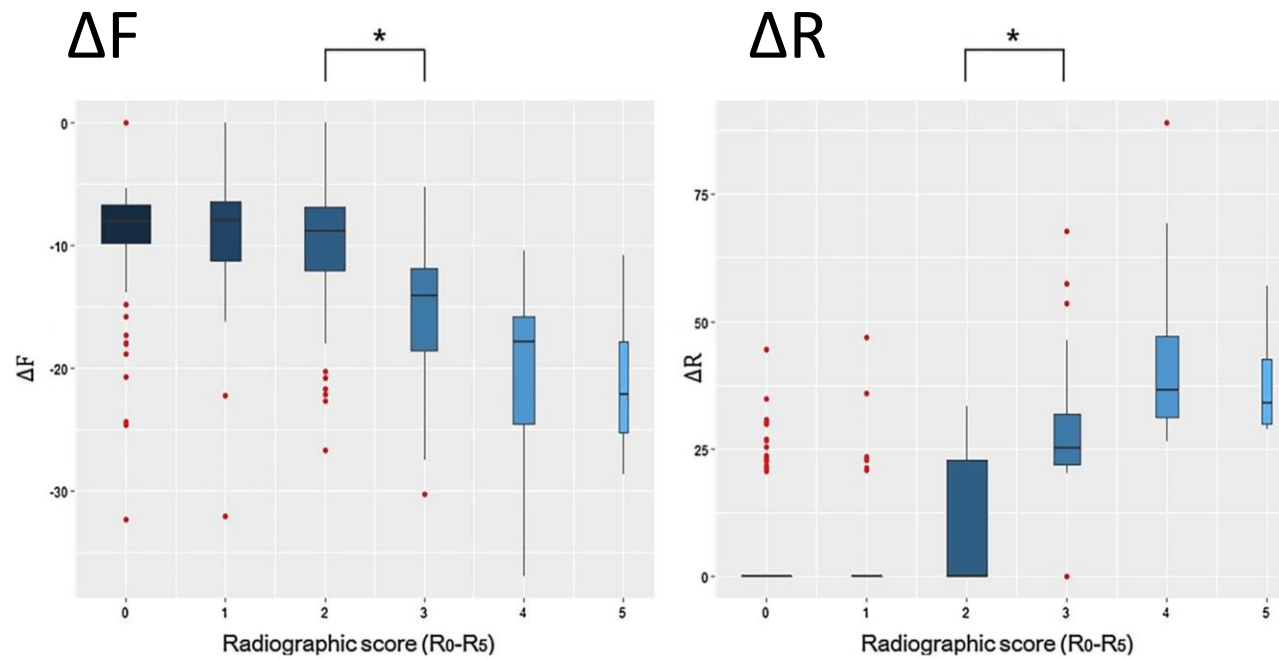

- Radiographic (bitewing)
- Visual tactile (ICDAS)
- **QLF (ΔF , ΔR , QS-proximal)**

QS-Proximal value	Description	Examples	White-light images	Fluorescence images
Q0	No fluorescence change			
Q1	Irregular dark shadow but no red fluorescence			
Q2	Faint red fluorescence limited in 1/3 of ucco-lingual width			
Q3	Strong red fluorescence over the 1/3 of ucco-lingual width			

Validity of QLF parameters

	ΔF	ΔR
Cut-off points	-12.4	23.3
Sensitivity	0.825	0.842
Specificity	0.816	0.879
AUROC (95% C.I.)	0.860 (0.808–0.913)	0.902 (0.851–0.953)

Validity of QS-Proximal

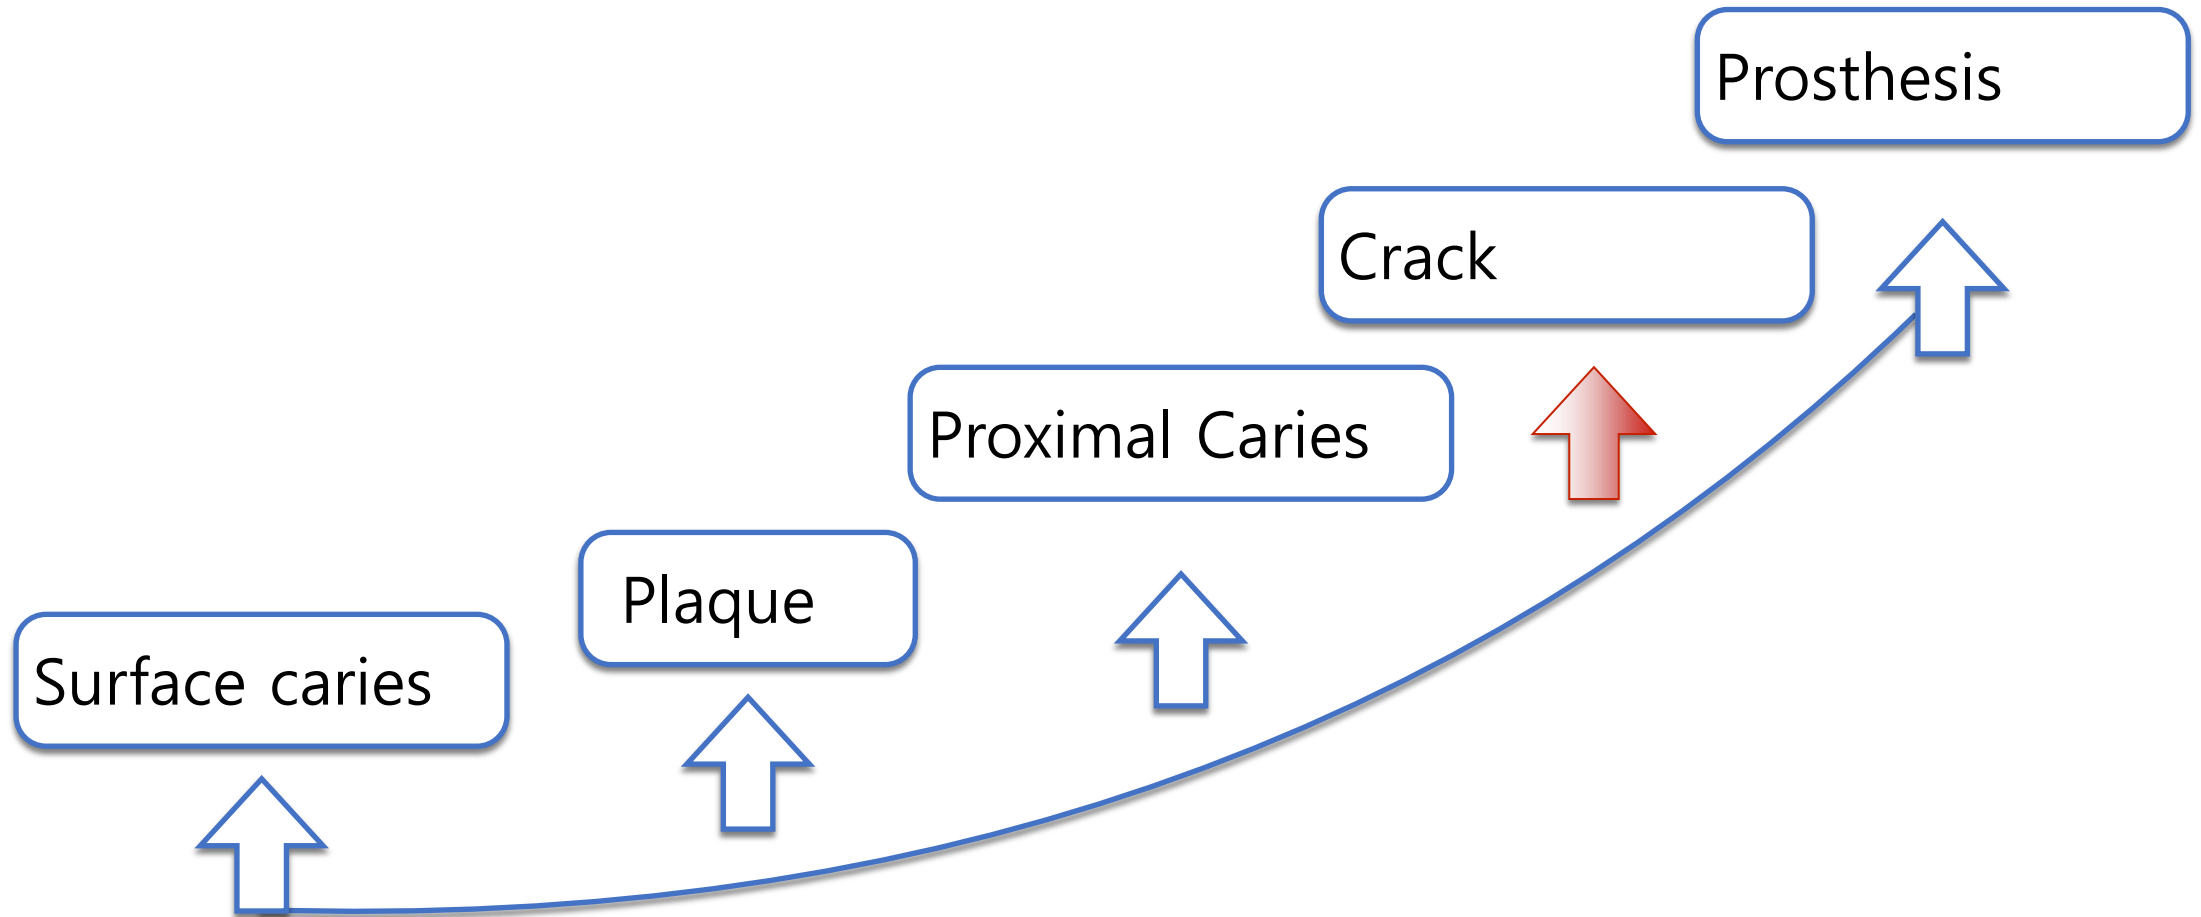

The sensitivity, specificity, and AUROC value of the QLF score (QS-Proximal) and visual score at different cut-off thresholds (Q_0/Q_1 , Q_1/Q_2) to detect proximal caries at the dentine level (R_{0-2}/R_{3-5}) measured by radiographic scores.

	QLF score (QS-Proximal)	
	Q_0/Q_1 (R_{0-2})	Q_1/Q_2 (R_{3-5})
Sensitivity	0.894	0.702
Specificity	0.834	0.951
AUROC (95% CI)	0.864 (0.810–0.919)	0.826 (0.753–0.900)

AUROC, area under the receiver operating characteristic curve; CI, confidence interval.
